

**MULTIPOLAR MAGNET TYPE GENERATOR FOR  
INTERNAL COMBUSTION ENGINES****CROSS REFERENCE TO RELATED CASE**

**[0001]** This application is a continuation in part of the application entitled "SINGLE-PHASE MULTI-POLAR MAGNET TYPE GENERATOR FOR VEHICLES" , Serial No. 09/742751, filed December 20, 2000 and assigned to the assignee hereof.

**BACKGROUND OF THE INVENTION**

**[0002]** This invention relates to a multipolar magnetic type machine such as a generator for an internal combustion engine and more particularly to an improved, compact and high output and efficiency generator of this type.

**[0003]** Many types of engines are associated with rotating electrical machines. For example the engine may drive a generator for generating electrical power for both engine operation and also for powering accessories of an associated vehicle. Generally, these types of generator employ relatively rotatably permanent magnets and coil windings surrounding armatures. The relative rotation induces an electrical current in the windings, which is extracted and, due to its alternating current characteristics, rectified for use in powering the DC electrical components associated with the engine and/or vehicle. Generally, the permanent magnets rotate and the member carrying the armature windings is fixed, although other types of relationships are possible.

**[0004]** In connection with this type of device and in accordance with modern practice, the demands of the generator continue to increase. Thus, in order to provide greater power output, it is necessary to increase the size of the generator and, accordingly, this results in the necessity of increased power of from engine to drive the generator. In many of the engine applications which such generating systems are employed, the engine also drives a vehicle that is quite compact in nature, such as personal watercraft, motorcycle or the like. Thus, the increase in size of the generator is not acceptable.

[0005] In addition, if the generator grows in size and mass, then the engine that powers it must be similarly increased in output. This can result in the increase in emissions from the engine and can result in engine performance that is less than satisfactory due to the power consumed by the generator.

[0006] It is, therefore, a principal object to this invention to provide an improved and compact rotating electrical machine of this type.

[0007] It is a further object to this invention to provide an improved generator that has a compact construction and yet high efficiency and high power output.

[0008] Conventionally the coil windings and specifically the armatures therefore have been manufactured by laminating blanks of a cold rolled steel plate. The cold-rolled steel plate is manufactured by rolling an acid-cleaned, hot-rolled coil to a thin rolled steel plate. Annealing and skin-pass rolling follow this step. The material is classified into three grades identified as SPCC, SPCD and SPCE according to JIS Standard, depending on the degree of workability. The SPCC plate is for general work, used extensively for parts of low workability, and also inexpensive. In conventional generators, a SPCC plate of 1.0mm thickness is used for the armature core.

[0009] The inventors hereof have discovered that the output of the generator and its size can be improved by optimizing the thickness of the laminations the armature core. A thinner electromagnetic steel plate decreases loss and thus increases efficiency, but smaller thickness will lower the ratio (space factor) of total cross-sectional area of core plates occupying in the cross-sectional area of the stator core.

[00010] Therefore, in accordance with this invention, the inventors have determined the optimum thickness so as to achieve maximum power output.

[00011] In connection with the use of the optimum thickness another factor is important in achieving the results of maximum efficiency and performance. It has also been discovered that the output of the generator is related specifically to the magnetization angle of one pole of the permanent magnet, as will be hereinafter defined. It has been found that the performance of the generator is significantly affected by this factor because of the non-linear sinusoidal output at the generator.

[00012] The permanent magnets of the machine generally are either formed on an annular member and may be adhesively affixed to it or may be formed by bonding an un-magnetized annular magnetic material to the rotor and thereafter magnetizing it so as to provide the alternating poles necessary to provide the circumferentially spaced magnetic poles. Post installation magnetization has not been preferred.

[00013] It has been discovered that there is a relationship between the magnetization angle, the angle occupied by a magnet with respect to the center of rotation of one pole of the permanent magnet and the output wave of the generator cause distortions which depend in magnitude on harmonic components contained within the output waveform. This is especially true in connection with harmonic components of the third harmonic or greater. This distortion in the output wave has been found to increase heat buildup and decrease efficiency of the generator.

[00014] Therefore, in accordance with another feature of this invention, the inventors have determined the optimum magnetic electrical angle ratio so as to achieve maximum power output with minimum power loss, heat generation and distortion.

#### **SUMMARY OF THE INVENTION**

[00015] This invention is adapted to be embodied in a rotating machine having a permanent magnet having changing pluralities in a circumferential direction at regular intervals and a relatively rotatable, associated element have a plurality of armatures around which coil windings are formed. In accordance with a main feature of the invention, the armature cores are formed laminations formed from an electromagnetic steel plate having a thickness in the range of 0.25-0.65mm.

[00016] In accordance with another feature of the invention, the magnetization angle of the poles of the permanent magnet is set with respect to the rotational axis to be in an electrical range of 120° to 140°.

#### **BRIEF DESCRIPTION OF THE DRAWINGS**

[00017] Fig. 1 is a cross-sectional view taken along the rotational axis of a rotating electrical machine constructed in accordance with an embodiment of the invention.

[00018] Fig. 2 is a view looking generally in the direction of the arrow 2 in Fig. 1 and shows the relationship of the armature cores to the permanent magnets.

[00019] Fig. 3 is a graph showing the relationship of the thickness  $t$  (mm) of an armature core plate and the index (%) of space factor ( $\alpha$ ) of the stator core.

[00020] Fig. 4 is a graphical view showing the relation between thickness  $t$  (mm) of the armature core plate and the index (%) of efficiency ( $\eta$ ) of the resulting generator.

[00021] Fig. 5 is a graphical view showing the relation between thickness  $t$  (mm) of the armature core plate and the index (%) of space factor  $\times$  efficiency = ( $\alpha\eta$ ).

[00022] Fig. 6 is a graphical view showing the relationship between the mechanical angle of the permanent magnet poles, the magnetic electrical angle and the electrical angle between the magnets as well as the harmonic variations in output.

[00023] Fig. 7 is a graphical view showing the actual variation in efficiency of the machine in accordance with the magnetic electrically angle.

#### **DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENT OF THE INVENTION**

[00024] Referring first to Figs 1 and 2 of the drawings, the reference numeral 11 indicates generally a rotating electrical machine constructed in accordance with an embodiment of the invention. In the illustrated embodiment, the machine 11 is comprised of a stator assembly, indicated generally by the reference numeral 12 and a rotor assembly, indicated generally by the reference numeral 13. In the illustrated embodiment, the machine 11 is an electrical generator but it is to be understood that the invention can be utilized with other types of rotating electrical machines and those wherein the permanent magnets are carried by the either the rotor and/or the stator.

[00025] The electrical machine 11 is particularly adapted to be utilized in conjunction with an internal combustion engine and, if acting as a generator, supplies an electrical power output from rotation of an engine output shaft, indicated by the reference numeral 14. The numeral 14 identifies an engine crankshaft of a small displacement engine that extends through a portion of the engine body and to which the electrical machine 11 is affixed in the manner, which will now be described.

[00026] The rotor 13 is comprised of a hub portion 15 that has an opening that receives one end of the crankshaft 14. A key way 16 is formed in the crankshaft 14 and receives a key 17 that has a spline connection to an internal bore 18 of the hub 15 so as to provide a non-rotational driving relationship there between. A nut 20, threaded onto a threaded end of the crankshaft 14 holds this assemblage together.

[00027] The hub portion 15 is affixed, by means of a plurality of circumferentially spaced rivets 19 to a flywheel carrying ring member 21. This ring member 21 is formed with a plurality of circumferentially spaced magnets 22 that comprise 6 having oppositely disposed and alternately placed poles so as to provide a total of 12 poles. The magnets 22 are held in spaced relationship to a radially extending inner wall 23 of the flywheel carrying ring member 21 by a spacer ring 24. If desired, a protective coating 25 may be formed on the inner surface of the flywheel carrying ring member 21 in surrounding relationship to the permanent magnets 22 so as to provide protection therefore.

[00028] The rotor magnets 22 are formed from disk-like magnet material (ferrite, alnico, or the like) that is bonded fixedly to the flywheel member 21 on its inside circumferential surface. This ring is then magnetized at angular intervals of  $30^\circ(360^\circ/12)$  by a magnetizer (not shown) such that  $0^\circ < \theta \leq 30^\circ$  where  $\theta$  is the magnetization angle (mechanical angle), as seen in Fig. 2. The polarity of adjacent magnetized portions is reversed. Alternatively, magnets with magnetization angle  $\theta = 30^\circ$  may be bonded at angular intervals of  $30^\circ$ . This construction is described in more detail later by reference to Figs. 6 and 7.

[00029] A starter gear 26 is connected to the hub portion 15 by means of a one-way clutch 27 that includes a carrier 28 that is fixed to the hub portion 15 by threaded fasteners 29. A suitable electrical motor (not shown) is associated with the starter gear 26 for starting of the associated engine by rotating the crankshaft 14.

[00030] The stator assembly 12 includes a laminated ring having a plurality of teeth, which form armature poles 31. Individual coil windings 32 are formed on bobbins 30 that extend around these poles 31 and are connected to a suitable external circuit for providing electrical output.

[00031] The stator 12 is made up of a plurality of laminated electromagnetic steel plates having a thickness in the range of 0.25-0.65 mm. These plates are stamped by press working and are coated with resin for insulation before lamination. This thickness is substantially less than has previously been used because such a thin plate is flexible and likely to be easily bent. This could cause that the tooth portions 31 to be turned up during blanking of press working, and the core plates may be connected less tightly to each other at the time of lamination, resulting in a possibility of easy separation.

[00032] In accordance with a feature of the invention, this is avoided by forming the sheets with an inner series of partially punched openings 33 and an outer series of partially punched openings 34, the latter being formed on the pole teeth 31. These partially punched openings 33 and 34 form holes and projections, which inter-fit with each other so as to line up the laminations in relationship to each other and to provide a mechanical coupling there between.

[00033] The stator 12 and specifically the hub portion thereof formed around a central opening 35 is provided with openings 36 for receiving threaded fasteners (not shown) that affix the stator 12 against rotation relative to a generator housing which is not shown, but which is affixed to the crankcase of the associated engine.

[00034] Figs. 3 and 4 show the relationship between the core space factor  $\alpha$  and efficiency  $\eta$  when the thickness  $t$  of the core plate of the stator core 31 is changed. Dot marks in these Figures show a result of actual measurement. Fig. 3 is a graph in which the space factor  $\alpha$  for the core plate thickness  $t$  of 1mm is represented as a reference value 100, and it can be seen from the graph that the space factor  $\alpha$  decreases for a smaller value of thickness  $t$ . This is because the degree of tightness of lamination is decreased due to warping or deformation for a smaller thickness  $t$  of the core plate.

[00035] To achieve a constant density of the magnetic flux passing through the stator core 31 for the same output current of the generator, the cross-sectional area of the magnetic path of the stator core 31 should be increased with decreasing space factor  $\alpha$ . Thus, the stator core 31 is increased in size for a smaller space factor  $\alpha$ .

[00036] Fig. 4 is a graph showing a result of actual measurement of variation of efficiency  $\eta$  with thickness  $t$  for a case (A) where an electromagnetic steel plate is used for blanks and case (B) where an SPCC plate is used for blanks. The measurement shows that the efficiency  $\eta$

increases for a smaller thickness  $t$  of the plate and is improved by about 5% for the case (A) of the electromagnetic steel plate compared with the case (B) of the SPCC plate. The reason why the efficiency  $\eta$  increases with decreasing thickness  $t$  would be that iron loss, particularly eddy-current loss, decreases with decreasing thickness  $t$ .

[00037] The calculated variation of space factor  $\times$  efficiency  $= \alpha\eta$  by using these results, as given in Fig. 5. Fig. 5 shows that  $\alpha\eta$  is largest for the thickness  $t$  in the range  $\beta$  of 0.25-0.65mm. The range  $\beta$  would be determined by a thickness (about 0.25mm) at which space factor  $\alpha$  changes abruptly and a thickness (about 0.65mm) at which efficiency  $\eta$  changes abruptly. In this invention, an electromagnetic steel plate are used for the stator core 31 on the basis of the foregoing measurement, the thickness of which is set to 0.25-0.65mm.

[00038] The magnet electrical angle  $\Theta$  of one pole of the permanent magnet 22 and the magnitude of harmonic components of the output wave form, have been analyzed by computer simulation and the results are shown in Fig. 6. This shows the maximum values (amplitude) of harmonic components A1, A5, A7 of the 3rd, 5th and 7th harmonics, respectively. This was obtained as a result of Fourier analysis of the output waveform.

[00039] Fig. 6 shows the fundamental component A1, but it has a period of  $360^\circ$  in electrical angle  $\Theta$  and thus need not be considered here. The harmonic components of even order such as the 2nd, 4th and 8th harmonics need not be considered because of positive and negative components of these harmonics are cancelled in the single-phase output.

[00040] The magnet electrical angle  $\Theta$  used here has the following relation to the mechanical angle  $\theta$  of a given magnetic pole. It is assumed that the frequency of the electromotive force is  $f$ ; an alternate voltage of  $p$  cycles is generated if a rotor with  $2p$  poles makes one revolution. The length of time a magnetic pole travels two pole pitches, is equivalent to the length of time the electromotive force (output voltage) completes one cycle.

[00041] That is, the mechanical angle of  $2\pi/p$  corresponding to the two pole pitches corresponds to the electrical angle (magnet electrical angle) of  $2\pi$ . Thus,  $p\theta = \Theta$ . "The electrical angle between magnets" in Fig. 6 is an angle of an unmagnetized portion or a gap produced between adjacent permanent magnets 22 as the mechanical angle  $\theta$  of the permanent magnet 22 becomes small, and it is represented as  $(180 - \Theta)/2$ .

[00042] As a result of the analysis, the amplitude (wave height) of the 3rd, 5th and 7th harmonic components is compared; the largest component is determined as a maximum value  $A_{\max}$  of the harmonics. Also, taking as a reference the maximum value  $A_{\max}$  (0.424) of the harmonics at the electrical angle of  $\Theta=180^\circ$ , the ratio B ( $B=A_{\max}/0.424$ ) of the maximum value to the reference 0.424 is determined.

[00043] From this it has been found that a range  $\Theta_{\text{opt}}$  of the electrical angle  $\theta$  is optimum in which the ratio B is smaller than about 0.5. That is, it is verified that if the magnet electrical angle  $\Theta$  is set within this range  $\Theta_{\text{opt}}$ , the distortion of the output waveform due to harmonic components is smaller, the waveform is smoother, and thus efficiency of the generator is improved.

[00044] From Fig. 6, it can be seen that the range  $\Theta_{\text{opt}}$  of the electrical angle  $\theta$  is preferably  $122^\circ < \Theta < 140^\circ$  for the ratio B below 0.5. However, taking account of the ratio increasing sharply for the electrical angle  $\Theta$  below  $120^\circ$ , it may be reasonable to consider that the optimum electrical angle range  $\Theta_{\text{opt}}$  includes the electrical angle up to  $\Theta=120^\circ$  which is the angle just before the commencement of the sharp increase.

[00045] Therefore, the preferable electrical angle range  $\Theta_{\text{opt}}$  can be expanded as  $120^\circ < \Theta < 140^\circ$ . As a result, the magnet electrical angle range of  $120\text{--}140^\circ$  in that taking as a reference the maximum value of the harmonic components at the magnet electrical angle of  $180^\circ$ , a magnet electrical angle range is optimum in which this maximum value is approximately 50% or smaller of the reference as seen in Fig. 7, which shows actual measured values.

[00046] Thus, it should be apparent that the described embodiment of the invention provides a very compact yet high output and high efficient rotating electrical machine, which can be utilized, for example, as a generator in associated with small or medium displacement internal combustion engines. Of course, the invention is subject to other types of electrical machines without departing from the spirit and scope of the invention, as defined by the appended claims.
